(54) **Identification and selection of audio channels**

(57) A method for assigning a channel identification (ID) of an audio signal by which it is possible to follow up and select the audio channel selected by a user even though a program or an audio data stream is changed in an audio/video (A/V) device for reproducing a program including a plurality of audio data streams, a method for selecting audio channels using the same, and an apparatus suitable therefor are provided. The method for selecting the audio channels of an A/V data stream including a plurality of programs, comprises the steps of (a) when a program is changed to another program, searching whether there is a sub-audio data stream hav-

ing a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the program which was being reproduced before the program was changed, in the changed program and (b) when it is determined that there is the sub-audio data stream having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the program which was being reproduced before the program was changed in the step (a), selecting the sub-audio data stream. According to the method for selecting an audio signal, it is possible to follow up the voice mode selected by a user although a program or an audio data stream is changed.

**FIG. 5**

EP 1 113 435 A1

## Description

[0001] The present invention relates to a method for assigning an audio channel identification (ID) by which it is possible to follow up and select the audio channel selected by a user even when a program or an audio data stream is changed in an audio/video (A/V) device for reproducing a program including a plurality of audio data streams, a method for selecting an audio channel using the same, and an optical recording and reproducing apparatus suitable therefor.

[0002] Currently, a moving picture engineering group (MPEG) and AC3 are often used as a method for compressively encoding an audio signal. In a linear pulse code modulation (PCM), the audio signal is not compressively encoded but recorded as it is. In digital TV broadcasting or video CDS and digital video disks (DVDs) which are digital A/V devices, the MPEG is mainly used.

[0003] When the encoded data streams of MPEG A/V data and other data streams are integrated and applied to a real application, it is necessary to make a data stream by integrating these data streams. Auxiliary data can be additionally used according to a certain application. The roll of the MPEG system is synchronizing and multiplexing video and audio data.

[0004] In the MPEG system, multiplexing by packets is adopted. Each of the video and audio data is divided into data streams called packets having an appropriate length, information such as headers are attached to the packets, and the packets of the video and audio data are multiplexed.

[0005] The packets include information for identifying whether the data items are video or audio data in a region called a packet header as shown in Figure 1. The length of the packet depends on a transmission medium or application.

[0006] Table 1 illustrates the contents of the packet headers shown in Figure 1.

Table 1

Main items	
Packet_start_code_prefix	"00 00 01" h
stream_id	1 byte, for distinguishing kinds of data items
PTS value	
(DTS value)	
Data	Video data, MPEG audio data or private data

[0007] In Table 1, Packet\_start\_code\_prefix represents the start of a packet and stream\_id represents kinds of data items in a packet. For example, in the case of video data, stream id is a binary code "1110 0000" b. In the case of audio data, stream\_id is a binary code "1100 0\*\*\*" b. Here, "\*" shows that eight kinds of data streams can exist from 000b to 111b. In the MPEG system, other data items besides the two data items are classified as private streams. A code "1011 1101" b can be used for the private stream.

[0008] A presentation time stamp (PTS) and a decoding time stamp (DTS), defined in the MPEG system standard, respectively represent time taken to output and decode a presentation unit in the video or audio data. The presentation unit is a frame of a picture in the video data and a frame of audio in the audio data. The DTS is not necessary in the case of the audio data.

[0009] Except MPEG audio data, audio data such as AC3 or LPCM is realized by private streams. The content of the packet header adopted to the private streams is shown in Table 2.

Table 2

Main items	
Packet_start_code_prefix	"00 00 01" h
stream_id	"1011 1101" b
PTS value	
substream_id	AC3 or LPCM
number_of_audio_channels	Number of audio channels
Data	

[0010] In the Table 2, the substream\_id is used in order to distinguish the kinds of audio data encoding such as AC3

or LPCM. For example, in the case of the AC3, the `stream_id` is "1010 0\*\*\*"b. Here, \*\*\* means that up to eight data streams can exist like in the MPEG audio. In the MPEG system, one program can have various video data streams and audio data streams.

[0011] The term "number\_of\_audio\_channels" denotes the number of channels. There can be 1ch, 2ch, 3ch, 4ch, and a dual mono channel. Here, channels are different from channels selected by a user. Namely, the above channels appear as one channel to the user excluding the dual mono. The dual mono is recognized as two channels.

[0012] In a MPEG-1 or MPEG-2 program stream (PS), an upper layer of the video or audio packet, called a pack, exists. In general, a pack formed by integrating a plurality of packets is considered to be a basic unit. Figure 2 shows the structure of the pack. Additional information for a time based reference for synchronous reproduction exists in a pack header.

[0013] Table 3 shows the contents of the pack header shown in Figure 2.

Table 3

Main items	
Pack_start_code	"00 00 01 BA"h
"01"	shows that data is MPEG-2
SCR value	
program_mux_rate	
pack_stuffing_length	

[0014] In the Table 3, the Pack\_start\_code is a code from which pack data starts. SCR value represents the time at which the pack data reaches the buffer of a decoder and is used to synchronize the system clock of an encoding port with the system clock of a decoding port. The program\_mux\_rate represents a transmission rate at which video, audio, and private data items are multiplexed and transmitted. In order to decode data correctly, the data must be transmitted at a transmission rate higher than the transmission rate. The pack\_stuffing\_length represents the number of dummy data.

[0015] Figure 3 schematically shows channels and audio signals corresponding thereto. As shown in Figure 3, audio signals are output through decoders. The data of the dual mono channel having outputs, the audio data of CH0 and the audio data of CH1 is similar to the 2ch data. However, the dual mono data is different from the 2ch data in that left and right audio signals are related to each other in the 2ch data, meanwhile CH0 and CH1 are separate audio signals in the dual mono data.

[0016] For example, Korean language audio data can be loaded into CH0 and English language audio data can be loaded into CH1 in the dual mono channel. Therefore, in general, only one of the two channels is output or the CH0 audio data and the CH1 audio data are output through a left speaker and a right speaker, respectively.

[0017] Figure 4 shows an example of an apparatus for decoding and outputting the data of the dual mono channel. When a select signal is 0, the apparatus shown in Figure 4 outputs CH0 audio as left audio and right audio. When the select signal is 1, the apparatus outputs CH1 audio as left audio and right audio. When the select signal is 2, the apparatus outputs CH0 audio and CH1 audio as left audio and right audio, respectively.

[0018] Figure 5 schematically shows a method of recording or reproducing a multi voice audio signal as dual mono audio data. The multi voice audio signal is formed of main audio data and sub-audio data. When data is recorded, the main audio data and the sub-audio data are encoded into an audio data stream through a multi-voice encoder. At this time, the main audio data is encoded into the CH0 audio data and the sub-audio is encoded into the CH1 audio data.

[0019] When data is reproduced, an audio data stream is decoded into the CH0 audio data and the CH1 audio data through a multi-voice decoder. The CH0 audio data is main audio data and the CH1 audio data is sub-audio data.

[0020] Here, it is assumed that a plurality of audio data streams exist. As an example, when two audio data streams exist in an A/V data stream, the user can select one among the two channels. When the selected audio data stream is dual mono data, that is, sub-audio data streams are included, the user can select two channels.

[0021] It is an aim of at least embodiments of the present invention to provide a method of assigning a channel identification (ID) to a sub-audio data stream included in an audio data stream when each audio data stream is in a dual mode in an audio/video (A/V) stream including a plurality of audio data streams.

[0022] It is another aim of at least embodiments of the present invention to provide a method of selecting the same kind of audio channel by following up the audio channel selection input of a user although a program or an audio data stream is changed in an A/V device for reproducing a plurality of audio data streams which allow a dual mono mode.

[0023] It is still another aim of at least embodiments of the present invention to provide an apparatus suitable for the above method of selecting audio channels.

**[0024]** According to the present invention there is provided a method of assigning audio channel IDs as set forth in claim 1 or claim 3 appended hereto. Also according to the present invention there is provided a method for selecting audio channels as set forth in claim 7 appended hereto. Further according to the present invention there is provided an optical recording and reproducing apparatus as set forth in claim 10 appended hereto. Preferred features of the present invention will be apparent from the dependent claims and the description which follows.

**[0025]** According to a first aspect of the present invention there is provided a method of assigning audio channel IDs, wherein channel IDs  $2n-1$  ( $n$  is the order of precedence of audio data streams, 1, 2, 3, ...) are assigned to audio data streams in an audio/video (A/V) data stream including at least two kinds of audio data streams, each of which is in a dual mono mode.

**[0026]** Preferably, channel numbers of dual mono data streams included in the audio data stream are  $2n-1$  in the case of main audio data streams and  $2n$  in the case of sub-audio data streams.

**[0027]** According to a second aspect of the present invention there is provided a method for assigning audio channel identifications (ID) A/V data stream including at least two audio data streams, each of which includes at least two sub-audio data streams, wherein different channel IDs are assigned to the respective sub-audio data streams.

**[0028]** Preferably, the IDs of the sub-audio data streams are a series of numbers according to the order of precedence.

**[0029]** Preferably, the order in which main audio data streams are generated is a first order of precedence and the order in which sub-audio data streams are generated is a second order of precedence, in the order of precedence.

**[0030]** Preferably, the IDs of the audio data streams are the same as the lead channel IDs of the sub-audio data streams included in the audio data streams.

**[0031]** According to a third aspect of the present invention there is provided a method for selecting audio channels of an A/V data stream comprising a plurality of programs, each program comprising at least two kinds of audio data streams, each audio data stream comprising at least two sub-audio data streams which are not repeated and have a series of IDs according to a predetermined order of precedence, comprising the steps of when a program is changed to another program, searching whether there is a sub-audio data stream having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the program which was being reproduced before the program was changed, in the changed program and when there is the sub-audio data stream having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the program which was being reproduced before the program was changed, selecting the sub-audio data stream.

**[0032]** Preferably, when there is no sub-audio data stream in the second program having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the first program the method further comprising the step of selecting a sub-audio data stream having a channel selection number which has first precedence among the sub-audio data streams of the second program.

**[0033]** Preferably, when there is no sub-audio data stream in the second program having the channel ID which is the same as the channel ID assigned to the sub-audio data stream of the second program the method further comprising the steps of: searching among the sub-audio data streams of the second program to determine whether there is a sub-audio data stream having a channel ID which has a lower precedence than the precedence of the channel ID assigned to the sub-audio data stream of the first program which was reproduced before the first program was changed; and when a sub-audio data stream exists, selecting, from the sub-audio data streams of the second program, the sub-audio data stream having the channel ID which has a lower precedence than the precedence of the channel ID assigned to the sub-audio data stream of the first program which was reproduced before the program was changed.

**[0034]** According to a fourth aspect of the present invention there is provided an optical recording and reproducing apparatus, comprising a pick-up unit for picking up an optical signal from a disk, an RF AMP for converting an optical signal generated by the pick-up unit into an electrical signal and extracting a servo signal and modulated data, a digital signal processor for outputting a compressed A/V data stream by demodulating the modulated data provided by the RF AMP, a servo unit for receiving information from the RF AMP required for controlling a servo and the system controller and performing a servo operation, an AV codec for decoding the compressed A/V data stream provided by the digital signal processor and outputting an A/V data stream including a plurality of audio data streams, a key input unit for inputting the key input of a user, and a system controller for performing user interfacing through the key input unit and controlling the pick-up unit, the RF AMP, the digital signal processor, and the AV coded, wherein the system controller searches whether there is a sub-audio data stream having the same channel ID as the channel ID assigned to the sub-audio data stream of the program which was reproduced before the program was changed in the changed program when one program is changed to another program and selects the sub-audio data stream having the same channel ID as the channel ID assigned to the subaudio data stream of the program which was reproduced before the program was changed in the changed program.

**[0035]** For a better understanding of the invention, and to show how embodiments of the same may be carried into effect, reference will now be made, by way of example, to the accompanying diagrammatic drawings in which:

Figure 1 shows the structure of packets in an MPEG system;

Figure 2 shows the structure of a pack in the MPEG system;

Figure 3 shows audio signals in each channel;

Figure 4 shows an example of an apparatus for decoding and outputting the data of a dual mono channel;

Figure 5 schematically shows a method for recording and reproducing a multi voice audio signal as dual mono audio data; and

Figure 6 is a block diagram showing the structure of an optical recording and reproducing apparatus according to the present invention.

**[0036]** In a method of assigning an audio channel identification (ID) according to the present invention, a separate channel ID is assigned to each audio channel included in a program.

**[0037]** Table 4 shows examples of channel IDs assigned to data streams when three audio data streams are recorded on one program.

Table 4

	Non dual mono	Dual mono	
	Channel ID		Channel ID
Data stream 1	1	CH0	1
		CH1	2
Data stream 2	3	CH0	3
		CH1	4
Data stream 3	5	CH0	5
		CH1	6

**[0038]** In other cases excluding the dual mono case, channel IDs such as  $2n-1$  ( $n=1, 2$ , and  $3$ ) are given. At this time,  $n$  is the same as a data stream number. In the case of dual mono, channel IDs  $2n-1$  are given to CH0 data and channel IDs of  $2n$  are given to CH1.

**[0039]** When the user presses an audio change key through an apparatus such as a remote controller, numbers larger than the currently reproduced channel ID are sequentially selected and output. When the user selects a channel ID, the audio data stream corresponding to the ID is selected, decoded, and output.

**[0040]** In the audio channel selecting method according to the present invention, when a program is changed, the audio channel selected in a previous program is followed up and selected in a next program. Also, when there is no audio channel before changing the program, a default audio channel is selected.

**[0041]** Here, it is assumed that a new data stream is input when data is reproduced. Audio data different from a previous data stream may be recorded in the new data stream. For example, while one audio data stream, which is dual mono, is being recorded in the previous data stream, two data streams which are not dual mono are recorded in the new data stream.

**[0042]** In the audio channel selecting method according to the present invention, when data corresponding to a channel ID which is to be reproduced exists, the data is selected and reproduced. When there is no corresponding data, by default, the data corresponding to the channel ID-1 is selected and output.

**[0043]** When there is data corresponding to the channel ID which is being reproduced, the data is selected and reproduced. When there is no corresponding data, the current channel ID-1 is searched when the current channel is evenly numbered. When data corresponding to the channel ID-1 exists, the data is selected and output. When the data does not exist, the data corresponding to the channel ID 1 is selected and output. When there is no corresponding data and the current channel is oddly numbered, the data corresponding to the channel ID 1 is selected and output.

**[0044]** Table 5 shows another example of combinations of audio data streams.

Table 5

Program 1		Program 2	
Data stream 1 (dual mono)	CH0;channel ID 1	Data stream 1 (non dual mono)	Channel ID 1
	CH1;channel ID 2		
Data stream 2 (dual mono)	CH0;channel ID 3	Data stream 2 (non dual mono)	Channel ID 3
	CH1;channel ID 4		

[0045] For example, when the user presses an audio changing key during the reproduction of program 1, an output audio signal is changed in the order of CH0 of the data stream number 1, CH1 of the data stream number 1, CH0 of the data stream number 2, and CH1 of the data stream number 2.

[0046] When program 1 is reproduced by selecting CH0 of the data stream 2 whose channel ID is 3 and it is desired that the next program 2 be reproduced, it is investigated whether data of the channel ID 3 exists. Since the data stream 2 corresponding to the channel ID 3 exists in program 2, the data stream 2 is reproduced.

[0047] When the program 1 is reproduced by selecting CH1 of the data stream 2 whose channel ID is 4 and it is desired that the next program be reproduced, it is investigated whether the data of the channel ID 4 exists. Since there is no data corresponding to the channel ID 4 in the program 2, the data stream 1 whose channel ID is 1, which is the default channel, is selected and reproduced.

[0048] In another preferable method of changing channels, it is investigated whether there is a channel ID 3 obtained by subtracting 1 from a channel ID 4. When the channel ID exists, the channel ID is selected. When the channel ID does not exist, the data stream 1 whose channel ID is 1 may be selected and reproduced. In this case, since the data of the channel ID 3 exists, the data of the channel ID 3 is reproduced.

[0049] According to the method of the present invention, when the channel ID is oddly numbered, the channel is the main audio channel in non dual mono or dual mono. When the channel ID is evenly numbered, the channel is a sub-audio channel in dual mono.

[0050] When the user changes the audio channel, it is preferable to the user that the channel is changed regardless of whether the channel of the audio data is classified into separate audio data streams or classified as dual mono.

[0051] According to the audio channel selecting method of the present invention, when an audio changing key is received, the change from main audio to sub-audio is performed in the corresponding audio data stream and a change to the next audio data stream is performed.

[0052] When the user selects one audio channel, the currently selected channel is maintained even when the program is changed.

[0053] However, when there is no corresponding audio channel, the channel must be changed to an appropriate channel and the changed channel must be selected. At this time, CH0, which is the default channel, is selected and reproduced or the channel closest to the currently selected audio channel is searched for and then reproduced (when the channel ID is evenly numbered, namely, in the case of the sub-audio data, the main audio channel can be considered to be the closest channel, which is the oddly numbered channel ID-1).

[0054] Also, when there is no audio data stream corresponding to the currently set channel ID, the channel ID is stored and a basic channel is selected and output by the above-mentioned method or the closest channel is selected and reproduced, and when the audio data stream corresponding to the above channel ID appears, the data is selected and output.

[0055] This is done in case the user selects and reproduces a sub-audio channel, then selects and reproduces another program which does not have sub-audio for a short time, and selects and reproduces the original sub-audio when the program with the sub-audio is reproduced. By not doing so, the user must perform changing in order to reproduce the sub-audio.

[0056] Figure 6 is a block diagram of an optical recording and reproducing apparatus suitable for the present invention. A/V data is recorded and reproduced using a recordable disk. The function of the optical recording and reproducing apparatus can be divided into recording and reproducing.

[0057] During the recording of data, an AV codec 110 compressively encodes an A/V signal received from the outside by a predetermined compression scheme and provides information on the magnitude of the compressed data. A digital signal processor (DSP) 120 receives the A/V data supplied from the AV codec 110, assigns additional data for processing an error correction code (ECC), and performs modulation by a predetermined modulation scheme. A high frequency amplifier (RF AMP) 130 converts electrical data provided by the DSP 120 into an optical signal.

[0058] A pick-up unit 140 includes an actuator for recording the optical signal from the RF AMP 130 on the disk and performing focusing and tracking. A servo unit 150 receives information required for controlling a servo from the RF

AMP 130 and a system controller 160, and controls the servo.

[0059] The system controller 160 controls the entire system, determines the encoding mode of audio data, records data on a disk, and controls the data.

[0060] During the reproduction of data, the pick-up unit 140 picks up an optical signal from the disk on which data is stored. Data is extracted from the optical signal. The RF AMP 130 converts the optical signal from the pick-up unit 140 into an electrical signal and extracts a servo signal for controlling the servo and modulated data.

[0061] The DSP 120 demodulates the modulated data of the electrical signal provided by the RF AMP 130 corresponding to the modulation scheme used for modulating the data and removes additional data by performing the ECC. The servo unit 150 receives information required for controlling the servo from the RF AMP 130 and the system controller 160 and performs the servo operation.

[0062] The AV codec 110 decodes the compressed A/V data provided by the DSP 120 and outputs an A/V signal.

[0063] The system controller 160 performs user interfacing, for example, it processes the key input of the user, controls the pick-up unit 140, the RF AMP 130, the DSP 120, and the AV codec 110 by the above method, and analyzes an audio data stream and controls the pick-up portion 140, the RF AMP 130, the DSP 120, and the AV codec 110 so as to select and reproduce corresponding audio data when a command for changing the audio channel is received from a key input unit 170.

[0064] As mentioned above, according to the channel ID assigning method of the present invention, it is possible to follow up the same channel when an audio signal is selected by assigning different channel IDs to the channels of the audio data streams.

[0065] According to the audio channel selecting methods of the present invention, it is possible to follow up the audio mode selected by a user even when a program or an audio data stream is changed.

[0066] The reader's attention is directed to all papers and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

[0067] All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except combinations where at least some of such features and/or steps are mutually exclusive.

[0068] Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

[0069] The invention is not restricted to the details of the foregoing embodiment(s). The invention extend to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so disclosed.

## Claims

1. A method of assigning audio channel identifications (ID), wherein channel IDs  $2n-1$  ( $n$  is the order of precedence of audio data streams, 1, 2, 3, ...) are assigned to audio data streams in an audio/video (A/V) data stream including at least two kinds of audio data streams, each of which is in a dual mono mode.
2. The method of claim 1, wherein channel numbers of dual mono data streams included in the audio data stream are  $2n-1$  in the case of main audio data streams and  $2n$  in the case of sub-audio data streams.
3. A method for assigning audio channel identifications (ID) A/V data stream including at least two audio data streams, each of which includes at least two sub-audio data streams, wherein different channel IDs are assigned to the respective sub-audio data streams.
4. The method of claim 3, wherein the IDs of the sub-audio data streams are a series of numbers according to the order of precedence.
5. The method of claim 4, wherein the order in which main audio data streams are generated is a first order of precedence and the order in which sub-audio data streams are generated is a second order of precedence, in the order of precedence.
6. The method of claim 3, 4 or 5, wherein the IDs of the audio data streams are the same as the lead channel IDs of

the sub-audio data streams included in the audio data streams.

7. A method for selecting audio channels of an A/V data stream comprising a plurality of programs, each program comprising at least two kinds of audio data streams, each audio data stream comprising at least two sub-audio data streams which are not repeated and have a series of IDs according to a predetermined order of precedence, comprising the steps of:

(a) when a first program is changed to a second program, searching whether in the second program there is a sub-audio data stream having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the first program; and

(b) when it is determined that there is the sub-audio data stream in the second program having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the first program in the step (a), selecting the sub-audio data stream.

8. The method of claim 7, wherein when there is no sub-audio data stream in the second program having a channel ID which is the same as the channel ID assigned to the sub-audio data stream of the first program the method further comprising the step of selecting a sub-audio data stream having a channel selection number which has first precedence among the sub-audio data streams of the second program.

9. The method of claim 7, wherein when there is no sub-audio data stream in the second program having the channel ID which is the same as the channel ID assigned to the sub-audio data stream of the second program the method further comprising the steps of:

searching among the sub-audio data streams of the second program to determine whether there is a sub-audio data stream having a channel ID which has a lower precedence than the precedence of the channel ID assigned to the sub-audio data stream of the first program which was reproduced before the first program was changed; and

when a sub-audio data stream exists, selecting, from the sub-audio data streams of the second program, the sub-audio data stream having the channel ID which has a lower precedence than the precedence of the channel ID assigned to the sub-audio data stream of the first program which was reproduced before the program was changed.

10. An optical recording and reproducing apparatus, comprising:

a pick-up unit (140) for picking up an optical signal from a disk;

a radio frequency amplifier (130) for converting an optical signal generated by the pick-up unit (140) into an electrical signal and extracting a servo signal and modulated data;

a digital signal processor (120) for outputting a compressed A/V data stream by demodulating the modulated data provided by the amplifier (130);

a servo unit (150) for receiving information from the amplifier (130) required for controlling a servo and the system controller and controlling the servo;

an AV codec (110) for decoding the compressed A/V data stream provided by the digital signal processor and outputting an A/V data stream including a plurality of audio data streams;

a key input unit (170) for inputting the key input of a user; and

a system controller (160) for performing user interfacing through the key input unit (170) and controlling the pick-up unit (140), amplifier (130) the digital signal processor (120), and the AV codec (110),

wherein the system controller (160) searches a second program to determine whether there is a sub-audio data stream having the same channel ID as the channel ID assigned to the sub-audio data stream of a first program which was reproduced before the program was changed when the first program is changed to the

**ANNEX TO THE EUROPEAN SEARCH REPORT  
ON EUROPEAN PATENT APPLICATION NO.**

EP 99 31 0630

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report.  
The members are as contained in the European Patent Office EDP file on  
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
